25X1 [redacted]
F. C. Box FF
Kekaha, Kauai, T. H.

25X1 [redacted]
25X1 [redacted]
25X1 [redacted] was referred to the Honolulu Chest Clinic following his return from Japan.

In April, 1948 he was admitted to the 49th General Hospital in Tokio, Japan with a diagnosis of acute appendicitis. According to the report received from that facility, a diagnosis of pulmonary tuberculosis, chronic reinfection type moderately advanced, active, was made while he was a patient there.

Chest x-ray taken at the Honolulu Chest Clinic on 7/14/48 showed a minimal fibrotic calcific infiltration at the left apex. There was a fibre-calcific infiltration on the right side involving the apex, first, second and third anterior interspaces. The second film taken 8/18/48 showed no changes.

25X1 [redacted] was first known to this clinic in May, 1941 as a referral from Selective Service. His x-ray at that time showed fibrotic productive infiltrations in the same areas. Comparison between the present films and the films of 1941 showed fibrosis and calcification of the original lesions. Two gastric lavages were done on 7/26/48 and 8/2/48. At time of present writing the cultures are still negative for tubercle bacilli. Our studies to date have failed to show any signs of activity.

YOURS very truly,

MAURICE L. BRODSKY, M.D.
Acting Chief,
Bureau of Tuberculosis
